PROGRAMME: BSC.INFORMATION SCIENCE

My role as an Architect in my group

In software design and development, the role of me as an architect is central to ensuring that systems are well-structured, scalable, and aligned with both technical and business needs.

1. System Blueprinting

I will design the overall structure of the software defining how modules, components, and services interact. This “blueprint” guides developers and ensures the system is coherent and maintainable.

2. Technology Selection

As the architect I will evaluate and choose the right tools, frameworks, and platforms (e.g., databases, cloud services, programming languages). These decisions balance performance, cost, and long-term sustainability.

3. Standards and Best Practices

Architects establish coding standards, documentation rules, and design patterns. This ensures consistency across teams and reduces technical debt.

4. Focus on Non-Functional Requirements

Beyond features, they design for security, scalability, performance, and reliability**. For example, ensuring the system can handle thousands of users or recover quickly after failures.

5. Collaboration and Mentorship

I should act as a bridge between stakeholders and developers translating business requirements into technical solutions, communicating risks, and mentoring my group members

6. Long-Term Vision

Architects anticipate future needs and design systems that can evolve, integrate with other platforms, and remain relevant as technology changes
